

The pocket does not enlarge, wherever the ligand sits

Every published substrate- or detergent-bound MexB structure, measured in one common frame.

$r = -0.07$ between volume and depth; $+0.05$ between volume and ligand size.

Depth is arc length back from the periplasmic mouth along the widest ligand-free entry channel of the reference protomer, to the ligand centroid.

Each protomer superposed on 39 pocket-lining C-alpha of one reference, so the measuring sphere sits identically in every structure. Engineered MexB chimeras excluded.
